

Use Git Connector (Beta) to import content from Git repositories into Experience Manager Guides

[!IMPORTANT]

Git connector is currently available as a Beta feature, and remains disabled by default. Please contact the Customer Success team to enable the feature.

Git Connector enables you to integrate Git repositories with Experience Manager Guides. If you maintain certain documentation in Git repositories, you can bring that content into Experience Manager Guides and manage it as part of your documentation workflow.

After an administrator configures a Git connector for your source repository, you can import the folders, files, other documentation assets into Experience Manager Guides. Once imported, the content is stored and managed in Experience Manager Guides, where you can use its authoring, review, translation, and publishing capabilities to develop and deliver documentation.

The Git Connector also helps you keep imported content aligned with changes in the source repository. When content is updated in Git after it has been imported, you can refetch the changes in Experience Manager Guides, identify conflicts, and resolve them before updating the imported content. This enables you to work with Git-managed content in Experience Manager Guides while maintaining visibility into changes made in the source repository.

Prerequisites

Before you start using this feature, ensure that:

- Git Connector feature is enabled for your environment.
- *(If enabled)* Your Administrator has configured the Git connector in your environment. For details, view [Create and configure Git Connector from the user interface](#).
- You have access to the Git repository that contains the DITA content you want to import.
- You know which repository branch and source folder you want to use.
- You know the target folder in Experience Manager Guides where the imported content should be stored.

Import content from the connected Git repository

After your administrator configures the Git Connector, you can use it from the Editor to start importing content from a Git repository. Perform the following steps to import content from a Git repository:

1. In the Editor, open the left panel.

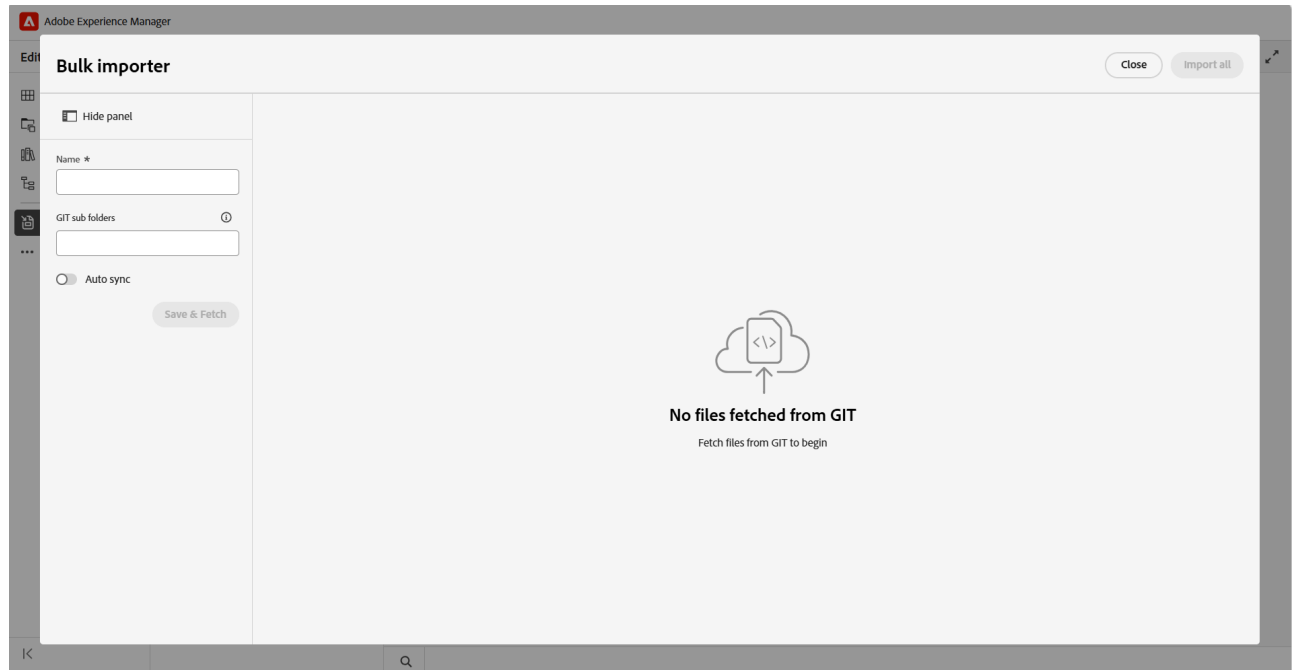

2. Select **Data sources**.

The connected data sources are displayed.

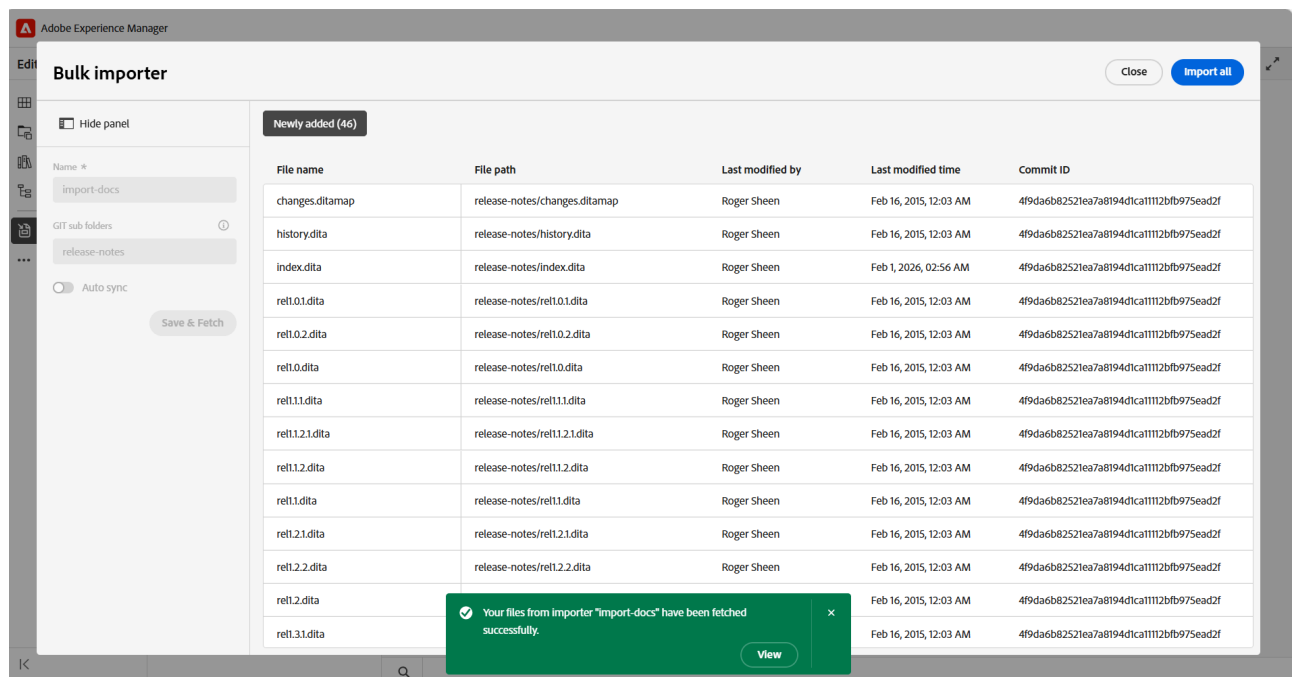

3. Select the Git Connector tile that your Administrator configured.

4. Select the + icon and then select **Bulk importer**.

The Bulk importer dialog is displayed.

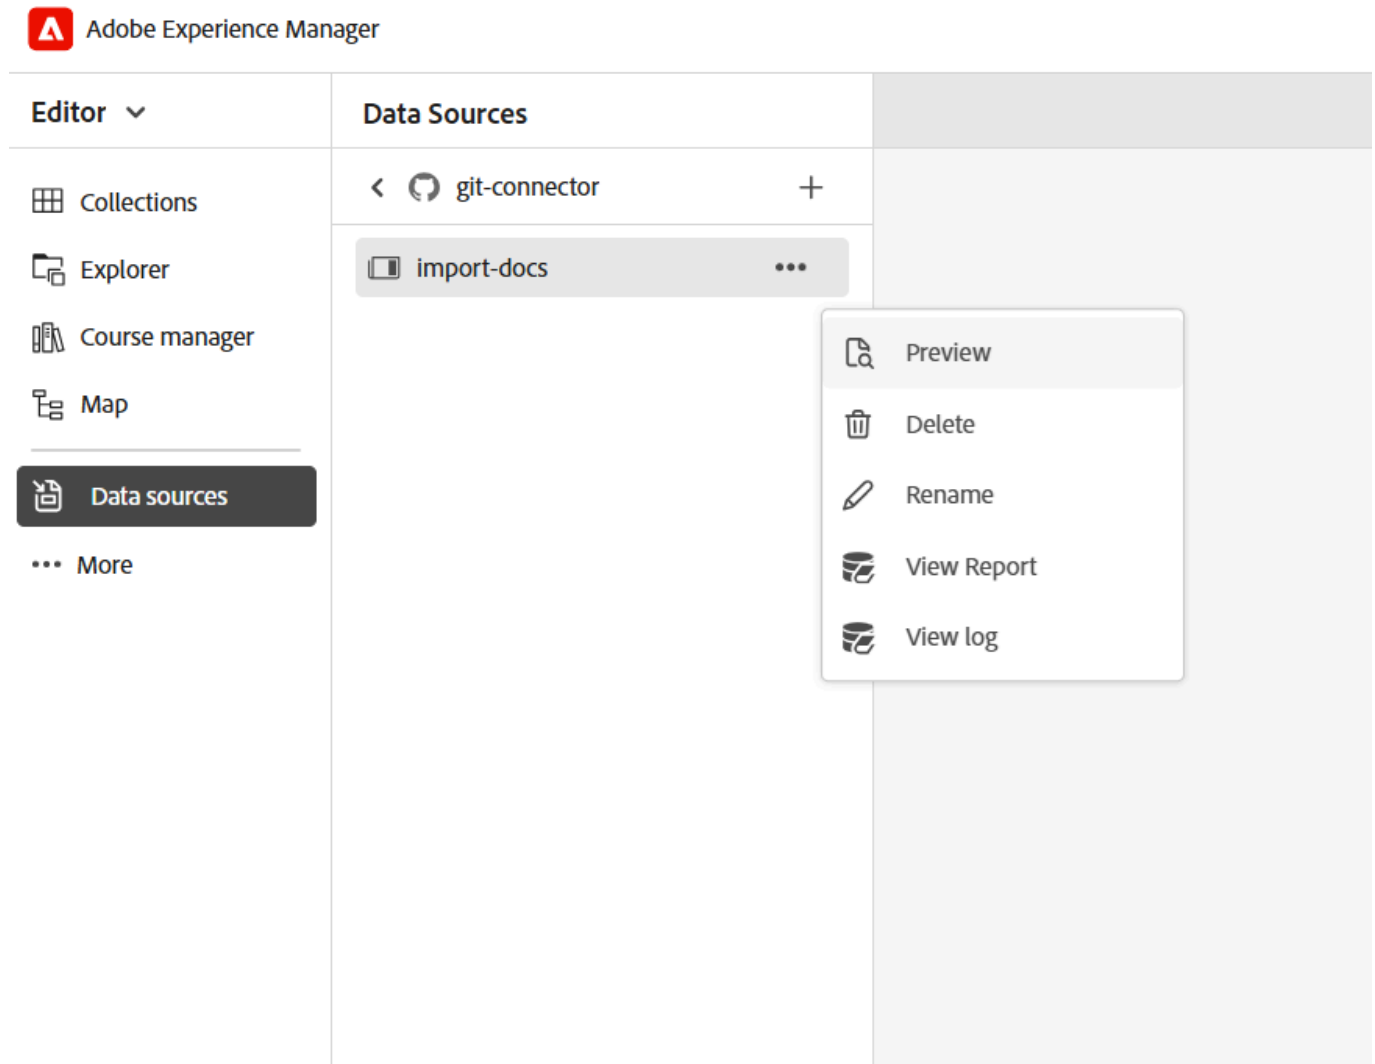

5. In the Bulk importer dialog, provide a name to the import, select a sub folder from your configured Git repository, and select **Save and Fetch**. The list of files available for import is displayed in the dialog. Review the list and validate the content before you continue.

6. After reviewing the files, select **Import all** to import the content into Experience Manager Guides. If you enable **Auto sync**, the files are imported automatically after you select **Save and Fetch**.

Manage Git-imported content

Once content is imported into Experience Manager Guides, you can use the available actions to manage the content and keep it synchronized with changes in the source repository.

{width="600"}

1. **Preview:** Preview imported content. If the source repository contains updates, review the differences and use the **Refetch** option to import the latest changes.
2. **Delete:** Remove imported content that is no longer required.
3. **Rename:** Rename imported content for easier identification.
4. **View log:** View the import log to review details of the import operation.
5. **View reports:** View and download the **Bulk import report**, which includes details such as:
 - total number of imported files
 - number of successful imports
 - number of failed imports

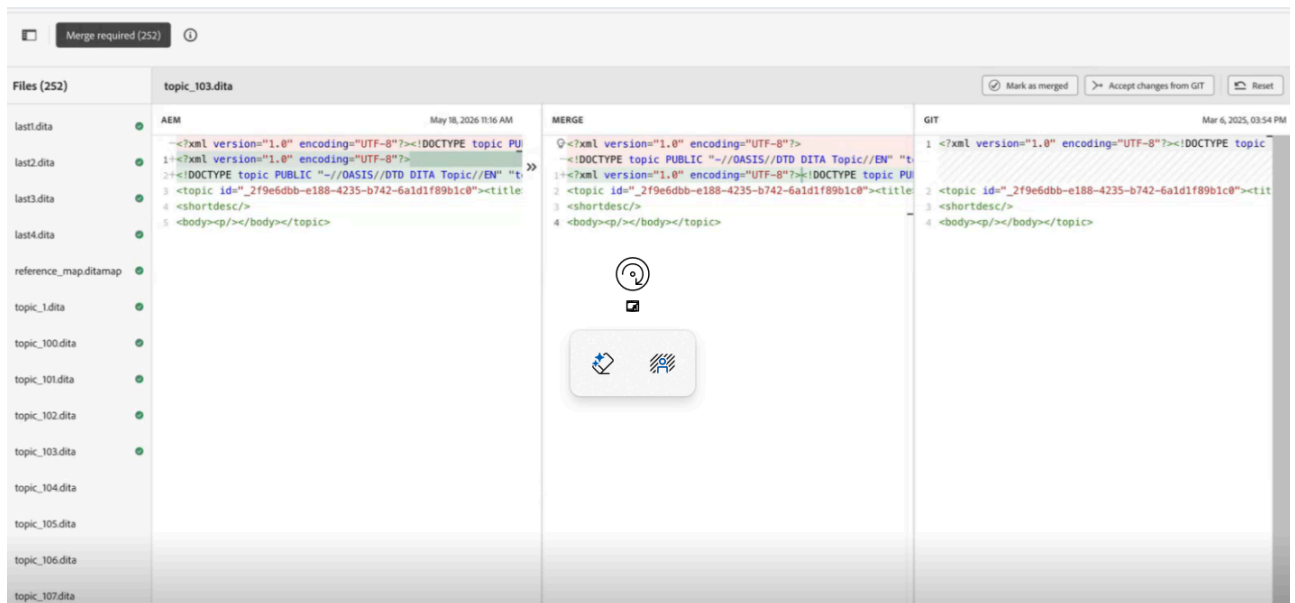

You can also download the detailed report. If some files fail to import, use **Retry failed imports** to try importing them again.

Review and resolve content conflicts

When you re-fetch content from a Git repository, differences in the content between the repository version and the corresponding content available in Experience Manager Guides are displayed as conflicts. You must resolve and merge such conflicts before importing the data into Experience Manager Guides.

Perform the following steps to resolve and merge conflicts:

1. Open the Bulk importer dialog and select **Refetch**.
2. If conflicts are detected, all the files containing the conflicts are listed. From the list, select a file that require review.
3. Review the content in the following sections:

{width="600"}

- In the **AEM** section, the current version of the content present in Experience Manager Guides is displayed.
 - In the **Git** section, the latest version of the content from the repository is displayed.
 - In the **Merge** section, the merged content is displayed.
4. Review the differences highlighted in the editor and perform one of the following actions:
 - Select **Accept changes from Git** to apply the repository changes to the merged version.
 - Review the merged content and select **Mark as merged** if no additional changes are required.

After all files containing the conflicts are marked as merged, the **Import all** button is enabled. Select **Import all** to complete the process of resolving conflicts.

If the repository contains entirely new content, such as a new topic, paragraph, or line that does not conflict with existing content, it is displayed under **Clean updates**. These updates do not require conflict resolution and can be imported directly.
